# Simultaneous determination of cetirizine, phenyl propanolamine and nimesulide using third derivative spectrophotometry and high performance liquid chromatography in pharmaceutical preparations

Fatma Ahmed Aly, Nahed EL-Enany, Heba Elmansi and Amany Nabil\*

## Abstract

**Background:** The combination between cetirizine (CET), phenylpropanolamine (PPA) and nimesulide (NMS) under trade name Nemeriv Cp tablet is prescribed for nasal congestion, cold, sneezing, and allergy. Among all published methods for the three drugs; there is no reported method concerning estimation of CTZ, PPA and NMS simultaneously and this motivates us to develop new and simple methods for their assay in pure form and tablet preparations.

**Results:** Two new methodologies were described for the simultaneous quantification of cetirizine (CTZ), PPA and NMS. Spectrophotometric procedures relies on measuring the amplitudes of the third derivative curves at 238 nm for CTZ, 218 nm for PPA and 305 nm for NMS. The calibration graphs were rectilinear over the ranges of 8–90  $\mu\text{g/mL}$  for CTZ, 20–100  $\mu\text{g/mL}$  for PPA and 20–200  $\mu\text{g/mL}$  for NMS respectively. Regarding the HPLC method; monolithic column (100 mm  $\times$  4.6 mm i.d) was used for the separation. The used mobile phase composed of 0.1 M phosphate buffer and methanol in the ratio of 40:60, v/v at pH 7.0. The analysis was performed using UV detector at 215 nm. Calibration curves showed the linearity over concentration ranges of 5–40, 10–100 and 10–120  $\mu\text{g/mL}$  for CTZ, PPA and NMS.

**Conclusion:** Application of the proposed methods to the laboratory prepared tablets was carried out successfully. The results were compared with those obtained from previously published methods and they were satisfactory.

**Keywords:** Third derivative spectrophotometry, HPLC, Cetirizine (CTZ), Phenylpropanolamine (PPA), Nimesulide (NMS), Tablets

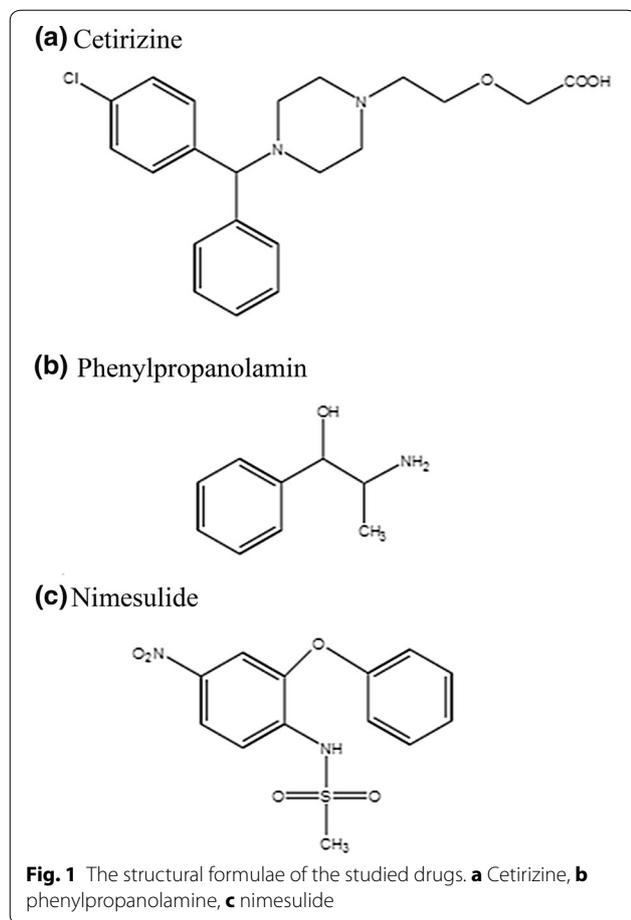

## Introduction

Cetirizine (CTZ, Fig. 1a); is non-sedating antihistamine with long acting activity for treatment of urticarial and rhinitis [1]. It is ([2-[4-[(4-chlorophenyl) phenylmethyl]-1-piperazinyl] ethoxy] acetic acid). The BP suggested a potentiometric titration method for determination of CTZ in its pure form; while it recommended an HPLC

method for both cetirizine oral solution and tablets [2]. Different analytical procedures were reported for its determination including HPLC [3–6], HPTLC [7], capillary electrophoresis [8] and spectrophotometry [9].

Phenylpropanolamine hydrochloride (PPA, Fig. 1b) is a nasal decongestant mainly used in combinations for relief of cold symptoms as it has indirect sympathomimetic activity [1]. Its chemical name is (1RS, 2SR)-2-amino-1-phenylpropan-1-ol. The BP described non aqueous potentiometric titration for PPA [2]. The USP suggested non-aqueous titration method using glacial acetic acid

\*Correspondence: amanyabil87@gmail.com  
Department of Analytical Chemistry, Faculty of Pharmacy, University of Mansoura, Mansoura 35516, Egypt

for PPA pure form and HPLC method for its capsules, extended released capsules, tablets, extended released tablets and oral solutions [10]. There are different methods used for PPA determination as HPLC [5, 6, 11], capillary gas chromatography [12], spectrophotometry [13] and flow injection [14] methods.

Nimesulide (NMS, Fig. 1c) is a non-steroidal anti-inflammatory that acts by inhibition of COX-2 enzyme [1]. It is 4'-nitro-2'-phoxymethanesulphonanilide. The BP mentioned potentiometric titration method for NMS [2]. The literature revealed several methods for NMS determination as HPLC [15–17], spectrophotometry [18] and TLC [19] methods.

The pharmaceutical preparation that contains the three drugs in a tablet dosage form is consisting of (5 mg CTZ, 25 mg PPA and 100 mg NMS) [20]. The current study deals with two simple and sensitive methods for the simultaneous estimation of the three analytes included in this tablet preparation. The spectrophotometric method is a simple and sensitive cost-effective method. It doesn't need any reagents or other tedious procedures. Although the literature contains two methods for the simultaneous

determination of both CTZ and PPA [5, 6]; our proposed HPLC method is superior to the both mentioned methods. Despite Sunil et al. [5] provides an HPLC method for application in plasma and urine, it is less sensitive than our proposed method. Suryan et al. method [6] seeks from the disadvantage of longer retention times, and broader peaks. Our proposed HPLC method, consequently is more sensitive, rapid with sharper peaks than the other mentioned methods owing to the use of monolithic column through this study.

## Experimental

### Apparatus

A Shimadzu (Kyoto, Japan) UV-1601 PC, UV-visible double-beam spectrophotometer was used. The third derivative spectra of the drugs were derived in the wavelength range (200–400) nm using  $\Delta\lambda = 8$  nm and scaling factor = 10.

A Shimadzu LC-20 AD prominence liquid chromatograph (Japan) was used for HPLC analysis; with a Rheodyne injector valve and a SPD-20A UV detector set at wave length 215 nm.

### Materials and reagents

Cetirizine hydrochloride pure sample was obtained from Apex Co., Cairo, Egypt (Batch No # 3003CZ8RJ) with 99.95% purity. Phenylpropanolmine hydrochloride (99.88% purity) was kindly brought from Cid Co., Egypt with Batch No # 41204. Nimesulide base was used with purity 99.90% as mentioned by the manufacturer, Batch No # 0006044. It is provided from Pharaonia Co., Alex, Egypt.

Organic solvents (HPLC grade) were purchased from Sigma-Aldrich (Germany).

Sodium hydroxide and sodium dihydrogen phosphate were purchased from ADWIC Co. (Egypt). Orthophosphoric acid (85%, w/v) was provided from Riedel-deHäen (Germany).

### Chromatographic conditions

Chromolith<sup>®</sup> performance (RP-18 monolithic, 100 mm × 4.6 mm i.d.) is the column used for the investigation. The mobile phase used is a mixture of methanol and buffer (0.1 M phosphate buffer) in a ratio of (60:40 v/v) respectively. The pH was adjusted to be 7. The flow rate was 1 mL/min and the wavelength was 215 nm.

### Standard solutions

CTZ, PPA and NMS 400 µg/mL stock solutions were prepared by dissolving 40 mg of each the studied drugs in 100 mL methanol and further dilution was carried out to achieve the required concentrations for each of the two methods.

## General procedures

### Construction of calibration graph

**Spectrophotometric method** Serial dilutions of stock solutions were prepared to give concentrations of 8–90, 20–100 and 20–200  $\mu\text{g/mL}$  for CTZ, PPA and NMS respectively. The third order derivative amplitudes were measured at 238, 218 and 305 nm for CTZ, PPA and NMS. A plot of the third derivative amplitude against the concentration was constructed to give the calibration curves.

**Chromatographic method** CTZ, PPA and NMS working standard solutions were prepared by serial dilution of the stock solution in a 10 mL flask to obtain final concentration ranges; 5–40  $\mu\text{g/mL}$  for CTZ, 10–100  $\mu\text{g/mL}$  for PPA, and 10–120  $\mu\text{g/mL}$  for NMS. The solutions were completed to the required volume by the mobile phase and were subjected to the chromatographic analysis under optimum conditions. Calibration graphs were constructed by plotting area under the curve against drug concentration in  $\mu\text{g/mL}$  [6–8].

### Analysis of CTZ, PPA and NMS laboratory-prepared mixtures

Mixtures of CTZ, PPA and NMS in the ratio of 1:5:20 were prepared within the concentration ranges and analysed by the spectrophotometric strategy or the chromatographic strategy under the optimum conditions described in “**Chromatographic conditions**”. The percent recoveries were determined using regression equations or calibration graphs.

### Analysis of CTZ, PPA and NMS in their co-formulated tablet

Laboratory co-formulated tablets were prepared as follows; accurately weighed 5 mg CTZ, 25 mg PPA and 100 mg NMS are mixed with 15 mg lactose, 10 mg magnesium stearate, 15 mg maize starch and 20 mg talc. One tablet was weighed, transferred to 100 mL volumetric flask, and completed to the mark with methanol. The solution undergoes 30 min sonication and then filtration till clear solution was obtained clear solution. Aliquots were taken within the concentration ranges for each drug (Table 1), and the chromatographic or spectrophotometric procedure was followed for calculating the percent recoveries [18].

## Results

### Third derivative spectrophotometric method

The simultaneous analysis of the three drugs by classical spectrophotometric method is a challenge owing to the strong overlapping of their zero order spectra (Fig. 2), and the difference between their concentrations in the tablet. Also there was strong overlapping in first and second order derivative spectra, third derivative spectrophotometry was used in the analysis of the three drugs mixture without interference from each other (Fig. 3). CTZ could be assayed by measuring its third derivative amplitude at zero crossing points of NMS and PPA at 238 nm (Fig. 4) and PPA could be determined at zero crossing points of CTZ and NMS at 218 nm (Fig. 5). Also NMS was determined at zero crossing points of CTZ and PPA at 305 nm (Fig. 6).

### Chromatographic method (HPLC)

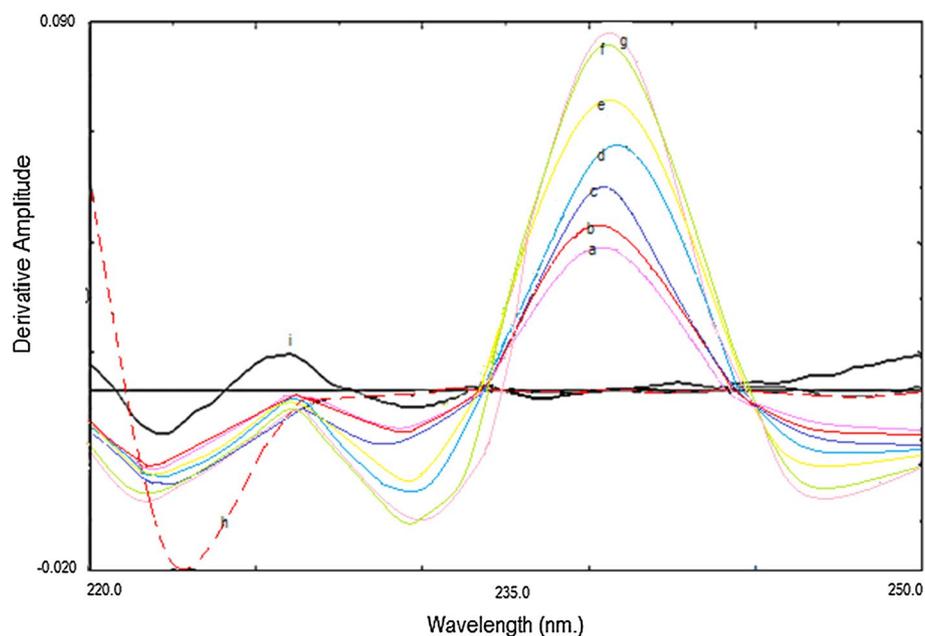

#### Optimization of the chromatographic performance

Studying of chromatographic conditions was carried out to reach the optimum conditions that achieve good and efficient separation. Figure 7 shows typical chromatogram for CTZ, PPA and NMS laboratory-prepared mixture and Fig. 8 shows the typical chromatogram for laboratory prepared tablet.

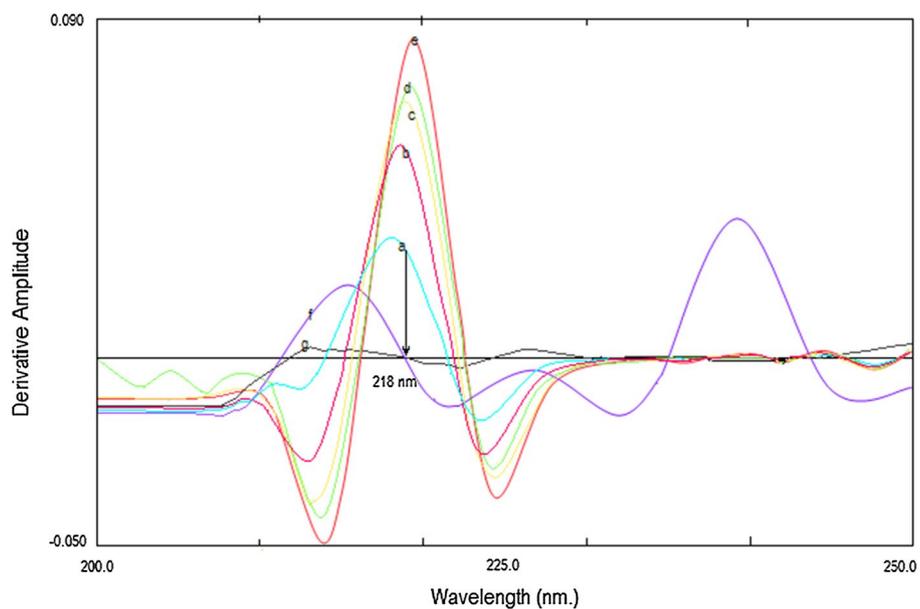

**Column choice** Reversed-phase Chromolith® performance (RP-18 monolithic, 100 mm  $\times$  4.6 mm i.d.) and

Promosil ODS 100 A column (250  $\times$  4.6 mm i.d. 5  $\mu\text{m}$  particle size) were tried during the separation. The first column was the suitable one as it resulted in well resolved peaks in shorter time.

**Appropriate wavelength choice** The UV absorption spectra of the studied drugs in methanol show maxima at 211 and 231 nm for CTZ, 218 nm for PPA and 238, 296 and 307 nm for NMS (Fig. 2). HPLC chromatograms for studied drugs were scanned from 200 to 400 nm to determine the suitable wavelength and it was

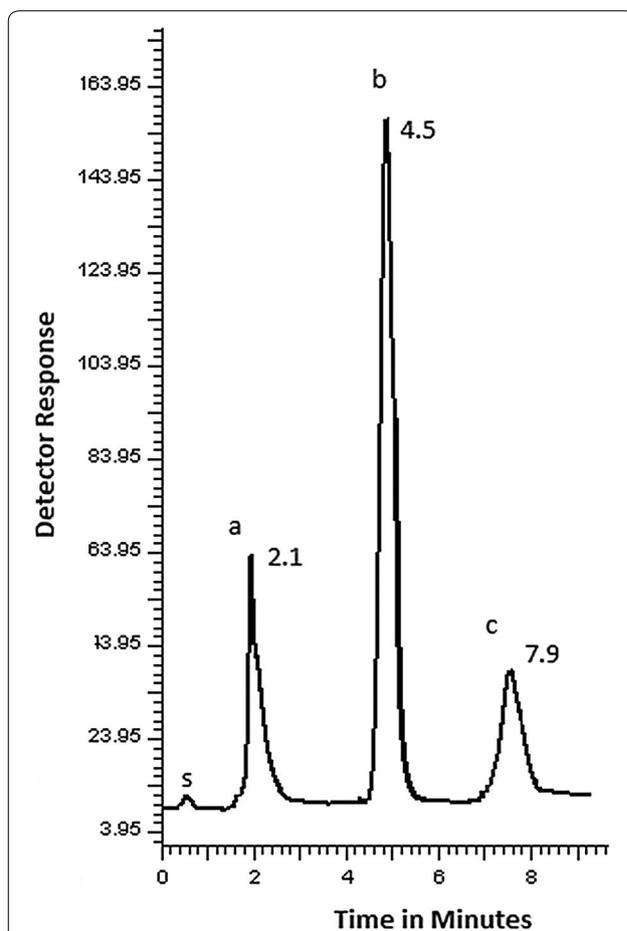

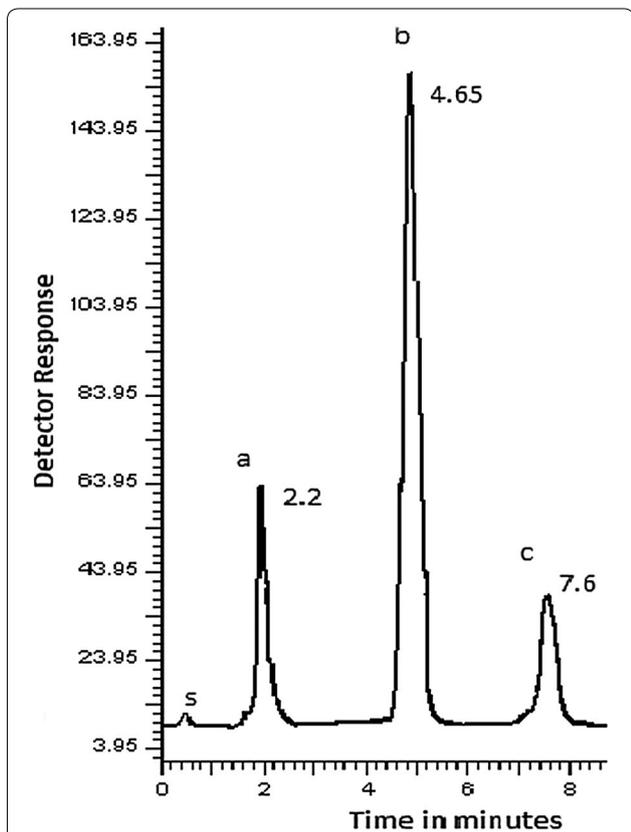

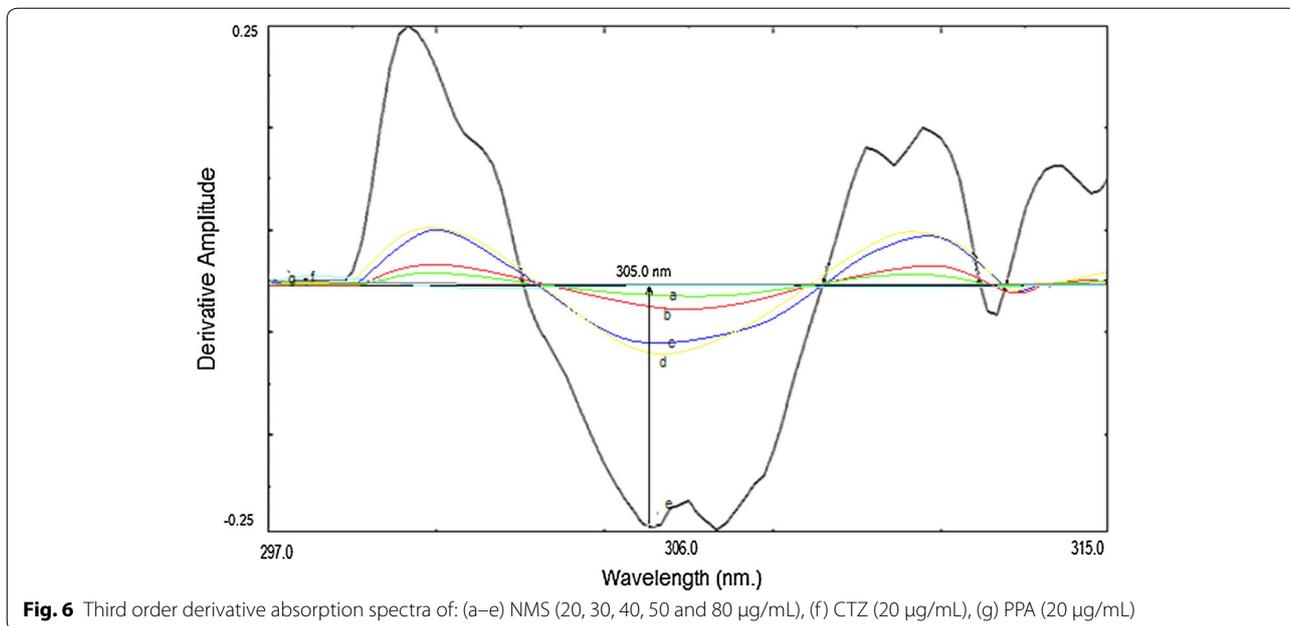

**Fig. 4** Third order derivative absorption spectra of: (a–g) CTZ (8, 10, 16, 20, 50, 60 and 90  $\mu\text{g/mL}$ ), (h) NMS (20  $\mu\text{g/mL}$ ), (i) PPA (20  $\mu\text{g/mL}$ )

**Fig. 5** Third order derivative absorption spectra of: (a–e) PPA (20, 40, 50, 80 and 100  $\mu\text{g/mL}$ ), (f) CTZ (20  $\mu\text{g/mL}$ ), (g) NMS (20  $\mu\text{g/mL}$ )

found that 215 nm was the suitable wavelength as the studied drugs showed high absorbance at this wavelength especially CTZ as it found in low concentration in the tablet dosage form.

*Mobile phase composition* Different modifications were done for the mobile phase to enhance the efficiency of the separation procedures as illustrated in Table 2.

#### Type of organic modifier

Upon studying different organic solvents; it was found that acetonitrile and n-propanol showed overlapping between solvent peak and PPA giving split peak. Methanol was selected for optimum chromatographic conditions, as it gave higher number of theoretical plates with well resolved sharp peaks.

#### Ratio of organic modifier

The mobile phase which gives rapid separation of CTZ, PPA and NMS in good resolution is methanol: 0.1 M phosphate buffer in the ratio (60: 40, v/v). As the ratio of methanol increased the retention time of CTZ, PPA and NMS was decreased. The ratios 70 and 80% v/v of methanol caused overlapping between CTZ and NMS. CTZ band broadening was observed with ratio 50% (Table 2).

#### Ionic strength of phosphate buffer

0.1 M phosphate buffer was used as it gave the highest number of theoretical plates with good resolution. Decreasing or increasing the ionic strength of phosphate buffer results in lower resolution or overlapping peaks.

#### Validation of the method

##### Data analysis

A linear relationship was established by plotting either the peak area or the derivative amplitude against the drug concentration in  $\mu\text{g/mL}$  for the HPLC and the spectrophotometric method respectively. The ranges of linearity were shown in Table 1. Equations referred to linear regression analysis are explained here:

The value of tabulated *t* and *F* are 2.20 and 19.29, respectively at *P* = 0.05 [21]

#### Third derivative spectrophotometric method:

$${}^3D_{238} = 0.0062 + 0.001 C \quad (r = 0.9999) \quad \text{for CTZ}$$

$${}^3D_{218} = -0.0283 + 0.002 C \quad (r = 0.9999) \quad \text{for PPA}$$

$${}^3D_{305} = -0.0362 + 0.002 C \quad (r = 0.9999) \quad \text{for NMS}$$

where: ( ${}^3D_{\text{wavelength}}$ ) is the third derivative amplitude of the spectra at the cited wavelength, and (*C*) is the concentration in µg/mL.

#### HPLC method:

$$P = 13024 + 42399 C \quad (r = 0.9999) \quad \text{for CTZ}$$

$$P = 492562.9 + 31015 C \quad (r = 0.9998) \quad \text{for PPA}$$

$$P = -72167 + 93428 C \quad (r = 0.9999) \quad \text{for NMS}$$

where: *P* is the peak area, *C* is the concentration of the drug in µg/mL and *r* is the correlation coefficient.

Theoretical basis assumes that the standard curve may be close to the origin, but practically it is rather difficult due to the presence of a reading for the solvent or the blank reading. As the intercept decreases in the calculations, this reflects that the solvent reading is almost near to zero [21]. Linearity of the calibration curves was proved through statistical analysis [21] of the data (Table 1).

The limit of quantitation and limit of detection were calculated according to ICH recommendations [22].

120	98.52 $\pm$ 0.95	0.96	0.55	100.24 $\pm$ 0.87	0.87	0.5

Each result is the average of three separate determinations

$$\text{LOQ} = 10 S_a/b \quad \text{LOD} = 3.3 S_a/b$$

where  $S_a$  is the standard deviation of the intercept of the calibration curve and  $b$  is the slope of the calibration curve. LOQ and LOD values for CTZ, PPA and NMS by the proposed methods were mentioned in Table 1.

In terms of accuracy; the results generated from the proposed methods were compared with those of well-established previous reports methods. The comparison method for CTZ and PPA describes reversed phase HPLC method [6] for simultaneous determination of both drugs using  $C_{18}$  column with UV detection at 217 nm. Concerning comparison method for determination of NMS; HPLC method [15] was utilized acetonitrile: 0.05M  $\text{KH}_2\text{PO}_4$ . The detection was carried out at 230 nm on  $C_{18}$  column. Accuracy was assessed through comparing the results of the proposed and the comparison methods and there was non-significant difference between the performance of them (Table 3). The ratio of

CTZ, PPA and NMS in the tablet is not covered in the comparison method.

Repeatability and intermediate precision were tested to verify the precision of the proposed methods and the results were summarized in Table 4.

#### **Robustness (for the HPLC method)**

Some variables were changed on constancy of others for robustness investigation. These variables included; pH ( $6.9 \pm 0.1$ ) and phosphate buffer concentration ( $0.1 \pm 0.005$  M). These small changes had no effect on the separation and resolution of CTZ, PPA and NMS. This gave a good indication for the reliability of the proposed method.

#### **Application in pharmaceutical preparations**

##### **Analysis of laboratory prepared mixtures**

A successful determination for the three drugs in their laboratory prepared mixtures was performed and summarized in Table 5.

**Table 5 Assay results for the determination of the studied drugs in different synthetic mixtures in different pharmaceutical ratios**

Each result is the average of three separate determinations

The value of tabulated *t* and *F* are 2.92 and 19.00 respectively at  $P = 0.05$  [21]

### Dosage form analysis

Co-formulated tablets was also analyzed using the proposed HPLC and spectrophotometric methods as illustrated in Table 6. The results of statistical analysis were satisfactory as indicated by Student's *t* test and variance ratio *F* test [21].

### Discussion

Third derivative spectrophotometry was used to analyze CTZ, PPA and NMS without interference from each other (Fig. 3). This method is simple, sensitive and efficient alternative to spectrophotometric methods mentioned for each of the three drugs in the literature [9, 13, 18], as it doesn't need any reagents or additional time consuming steps.

The proposed approach also describes a novel HPLC method for the simultaneous determination of CTZ, PPA and NMS on a monolithic column. The established method is capable to separate the drugs with high efficiency and high resolution factor and within a short analysis time.

### Conclusion

The current work provides the first method for the simultaneous analysis of CTZ, PPA and NMS in their pharmaceutical formulations. The developed spectrophotometric method is simple, rapid and economic. The HPLC method is a sensitive, reliable and time-saving method where separation of the studied analytes is achieved in less than 8 min. Moreover, the proposed methods overcome the analytical problems raised by the ratio of CTZ, PPA relative to NMS (1:5:20) and therefore could be used in the analysis of their co-formulated tablets in quality control laboratories.

### Abbreviations

CET: cetirizine; PPA: phenylpropanolamine; NMS: nimesulide; ICH: international conference on harmonization; LOQ: limit of quantification; LOD: limit of detection.

### Authors' contributions

FA and NE planned and supervised the whole work. HM participated in the assay proposal, analysis and literature review. FA, NE and HM supervised the experimental work and participated in the assay design. AN carried out the practical part, collect the results and wrote the paper. All authors read and approved the final manuscript.

### Competing interests
